

ABSTRACT OF THE DISCLOSURE

5 A method and apparatus for predicting load addresses and identifying new threads
of instructions for execution in a multithreaded processor. A load prediction unit scans an
instruction window for load instructions. A load prediction table is searched for an entry
corresponding to a detected load instruction. If an entry is found in the table, a load
address prediction is made for the load instruction and conveyed to the data cache. If the
10 load addresses misses in the cache, the data is prefetched. Subsequently, if it is
determined that the load prediction was incorrect, a miss counter in the corresponding
entry in the load prediction table is incremented. If on a subsequent detection of the load
instruction, the miss counter has reached a threshold, the load instruction is predicted to
miss. In response to the predicted miss, a new thread of instructions is identified for
15 execution.
